Algebraic Properties of the Index of Invariant Subspaces of Operators on Banach Spaces

GEORGE CHAILOS

Abstract. For an operator \( S \) on a Banach space \( X \), let \( \text{Lat}(S, X) \) be the collection of all its invariant subspaces. We consider the index function on \( \text{Lat}(S, X) \) and establish various algebraic properties of it. Amongst others we show that if \( S \) is a bounded below operator, then

\[
\text{ind } M + \text{ind } N \geq \text{ind } (M \cap N) + \text{ind } (M \vee N).
\]

If, in addition, \( \text{ind } M = \text{ind } N = 1 \) and \( M \cap N \neq \{0\} \) then \( \text{ind } (M \vee N) = 1 \).

1. Introduction

If \( S \) is an operator on a Banach space \( X \), then a closed subspace \( M \) of \( X \) is called invariant for \( S \) if \( SM \subset M \). The collection of invariant subspaces of an operator \( S \) is denoted by \( \text{Lat}(S, X) \). It forms a complete lattice with respect to intersections and closed spans. One of the important notions in the general theory of operators, such as bounded below operators, is the index of an element in \( \text{Lat}(S, X) \), which is defined as follows. (This definition is taken from [1].)

Definition 1.1. The map

\[
\text{ind} : \text{Lat}(S, X) \rightarrow \{0\} \cup \mathbb{N} \cup \{\infty\}
\]

is defined as \( \text{ind } M = \dim (M/SM) \) and \( \text{ind } M = 0 \) if and only if \( M = \{0\} \). We say that \( M \) has index \( n \) if \( \text{ind } M = n \).

The index function plays an essential role in the study of invariant subspaces of Banach spaces. (For example, see an extensive study in [5] of index 1 invariant subspaces in Banach spaces of analytic

Key words and phrases. Free modules, index, invariant subspaces.
functions.) In this article we give various algebraic properties of the index function. Amongst others, and as a corollary to our main result, we show that if \( M, N \in \text{Lat}(S, X) \), \( \text{ind} M = \text{ind} N = 1 \) and \( M \cap N \neq \{0\} \) then \( \text{ind}(M \vee N) = 1 \), where \( M \vee N \) denotes the closed span of \( M \) and \( N \). (Equivalently, \( M \vee N \) is the closure of \( M + N \).) This result, but in not such a general setting as the one presented here, was proved by Richter ([5], Corollary 3.12), using operator theoretical tools and results from analysis. Here we prove it using only algebraic tools and a rather standard result from functional analysis.

2. Algebraic Properties of the Index Function

Theorem 2.1. Let \( R \) be a commutative ring with identity and let \( A, A', B' \) be free unitary \( R \)-modules such that \( A' \) and \( B' \) are free submodules of \( A \). Then

\[
\text{rank}(A/A') + \text{rank}(A/B') = \text{rank}(A/(A'\cap B')) + \text{rank}(A/(A'+B')).
\]

Proof. Consider the following sequence

\[
0 \rightarrow A/(A'\cap B') \overset{f}{\rightarrow} A/A' \oplus A/B' \overset{g}{\rightarrow} A/(A' + B') \rightarrow 0,
\]

where \( f([y]) = ([y], [y]), \) \( g([x], [y]) = [x - y] \) and \( [\cdot] \) denotes the equivalence class in the appropriate quotient module. We claim that the sequence above is exact.

To prove the claim we first show that \( f \) and \( g \) are well-defined homomorphisms. Letting \( [y] \in A/(A' \cap B') \) and \( x \in A' \cap B' \), we obtain that \( f([y + x]) = ([y + x], [y + x]) = ([y], [y]) \). Hence, \( f \) is well defined. Moreover, \( f \) is a homomorphism, since

\[
f([y] + [z]) = ([y] + [z], [y] + [z]) = ([y], [y]) + ([z], [z])
\]

\[
f(r[y]) = (r[y], r[y]) = r([y], [y]), \quad r \in R.
\]

Similarly, if \( ([x], [y]) \in A/A' \oplus A/B' \), and \( x_1 \in A', \) \( x_2 \in B' \), then

\[
g([x + x_1], [y + y_1]) = ([x + x_1] - (y + y_1])
\]

\[
= ([x - y] + (x_1 - y_1]) = [x - y],
\]

since \( x_1 - y_1 \in A' + B' \). Thus, \( g \) is well defined.
Moreover, \( g \) is a homomorphism, since
\[
g([x], [y]) + ([x'], [y']) = g([x] + [x'], [y] + [y'])
\]
\[
= g([x + x'], [y + y'])
\]
\[
= [(x + x') - (y + y')] = [x - y + x' - y']
\]
\[
= [x - y] + [x' - y']
\]
and
\[
g(r([x], [y])) = g([rx], [ry]) = [rx - ry] = r[x - y], \ r \in \mathbb{R}.
\]

It remains to show that \( \ker g = \text{im} f \). For this let \(([x], [y]) \in A/A' \oplus A/B'\) be such that \( g([x], [y]) = 0 \). Then \([x - y] = 0\), and thus \( x - y \in A' + B'\). This implies that \( x + A' = y + B'\), i.e., \([x]_{A/A'} = [y]_{A/A'}\) wherefore \(([x]_{A/A'}, [y]_{A/A'}) \in \text{im} f\), and hence \( \ker g \subset \text{im} f\).

Conversely, if \(([x], [y]) \in \text{im} f\) then \( x + A' = y + B'\) and hence \( x + A' + B' = y + A' + B'\). It follows that \( g([x], [y]) = [x - y] = 0\) so that \( \text{im} f \subset \ker g\). The proof of the claim is complete.

Since \( A/(A' + B')\) is a free module, it is in particular projective, and hence the above exact sequence splits (see [4]). Therefore
\[
A/A' \oplus A/B' = A/(A' \cap B') \oplus A/(A' + B').
\]
This immediately implies that
\[
\text{rank}(A/A') + \text{rank}(A/B') = \text{rank}(A/(A' \cap B')) + \text{rank}(A/(A' + B'))
\]
concluding the proof of the theorem. \( \Box \)

As every vector space is free over its ground field, the following is an immediate consequence of the above theorem.

**Corollary 2.2.** If \( X \) is a Banach space and \( S \) an operator on \( X \), for all \( M, N \in \text{Lat}(S, X)\)

\[
\text{ind} M + \text{ind} N = \text{ind}(M \cap N) + \text{ind}(M + N)
\]

In the case when \( S \) is a bounded below operator, like the shift operator on Banach spaces of analytic functions, the following holds.

**Lemma 2.3.** Suppose \( M, N \in \text{Lat}(S, X)\), where \( S \) is a bounded below operator on a Banach space \( X \). Then

\[
\text{ind}(M \vee N) \leq \text{ind}(M + N) \leq \text{ind} M + \text{ind} N.
\]
Proof. If either \( \text{ind} M \) or \( \text{ind} N \) is infinite, then there is nothing to prove. So we may assume that \( \text{ind} M < \infty \) and \( \text{ind} N < \infty \). Thus there are finite-dimensional subspaces \( M_1 \) and \( N_1 \) of \( M \) and \( N \), respectively, such that \( M = SM + M_1 \), \( N = SN + N_1 \), where \( \dim M_1 = \text{ind} M \) and \( \dim N_1 = \text{ind} N \). We find that
\[
M + N = SM + M_1 + SN + N_1 \\
= S(M + N) + M_1 + N_1 \\
\subseteq S(M \lor N) + (M_1 + N_1) \\
\subseteq M \lor N.
\]
Since \( S \) is a bounded below operator, its range is closed (see, e.g., [2], Proposition 6.4, chapter VII), and hence the second to last expression is the sum of a closed and a finite-dimensional subspace, hence it is closed. Since \( M + N \) is dense in \( M \lor N \) we obtain that the last inclusion in above is actually an equality. From this it follows that
\[
\text{ind}(M \lor N) \leq \dim(M_1 + N_1) = \text{ind}(M + N) \leq \text{ind} M + \text{ind} N.
\]
\[\square\]

The next theorem, which is our main result, follows immediately from Corollary 2.2 and Lemma 2.3.

**Theorem 2.4.** If \( X \) is a Banach space and \( S \) a bounded below operator on \( X \) then, for all \( M, N \in \text{Lat}(S, X) \),
\[
\text{ind} M + \text{ind} N \geq \text{ind}(M \cap N) + \text{ind}(M \lor N).
\]

**Corollary 2.5.** Suppose that \( M_1, M_2 \in \text{Lat}(S, X) \) are such that \( \text{ind} M_1 = \text{ind} M_2 = 1 \), where \( S, X \) are as in the previous theorem. If \( M_1 \cap M_2 \neq \{0\} \) then \( \text{ind}(M_1 \lor M_2) = 1 \).

**Proof.** If \( M_1 \cap M_2 \neq \{0\} \) then \( \text{ind}(M_1 \cap M_2) \geq 1 \). As \( \text{ind}(M_1 \lor M_2) \geq 1 \), Theorem 2.4 implies that \( \text{ind}(M_1 \lor M_2) = 1 \). \[\square\]

**Example 2.6.** In [5], Proposition (2.16 b), Richter considered the case where \( S \) is the shift operator on any Banach space \( B \) of analytic functions on an open and connected subset of the complex plane. He showed that if \( m \geq 2 \) and there is a space in \( \text{Lat}(S, B) \) of index \( m \), and furthermore if \( n_1, n_2 \in \mathbb{N} \cup \{\infty\} \), \( n_1 + n_2 = m \), then there are invariant subspaces \( N_1, N_2 \) such that \( \text{ind} N_i = n_i, \ i = 1, 2 \) and \( \text{ind}(N_1 \lor N_2) = \text{ind} N_1 + \text{ind} N_2 \). In these cases, Theorem 2.4 implies that \( \text{ind}(N_1 \cap N_2) = 0 \) and hence \( N_1 \cap N_2 = \{0\} \). Thus, \( N_1 \lor N_2 = \)
$N_1 \oplus N_2$. (For example, it is well known ([3], Corollary 6.5) that when $S$ is the shift operator on a weighted Bergman space on the unit disk, then for all $1 \leq m \leq \infty$ there are invariant subspaces of index $m$.)
